

Munandy Bakery

Monthly Quality & Weight Analysis Report April 2026

Executive Analysis

Munandy Bakery
Monthly Branch Performance Report
April 2026
Prepared by: Quality Control Audit Division

1. Performance Overview

April 2026 presented significant consistency challenges across all three branches of Munandy Bakery. No branch achieved an optimal batch rate above 60%, indicating a systemic issue with weight control throughout the network. Overweight batches dominated variance incidents at every location, suggesting that portioning processes are leaning heavy across the board. With average absolute variances ranging from 7.1g to 22.4g, product standardization remains a pressing concern that requires structured intervention.

2. Best Performing Branch

Bulawayo Branch recorded the strongest performance for April 2026, achieving the highest optimal consistency rate at 57.5% across 113 batches. While this figure still falls short of an acceptable standard, Bulawayo produced the fewest overweight batches (39) and maintained a moderate average absolute variance of 17.3g. Relative to its peers, Bulawayo demonstrated the most balanced output and is the closest to meeting quality benchmarks.

3. Worst Performing Branch

Mutare Branch recorded the weakest performance this period. Despite processing the highest number of batches (125), only 52.8% were classified as optimal. More critically, Mutare posted the highest average absolute variance at 22.4g, nearly three times that of Harare. The branch also recorded the highest underweight count (11), pointing to inconsistent portioning that swings in both directions. This level of variance presents both a product quality risk and a potential customer trust issue.

4. Concerning Areas

Harare Branch, while showing the lowest average absolute variance (7.1g), still achieved only 55.1% optimal output, meaning nearly half of all batches fell outside acceptable weight ranges. The overweight skew (49 batches versus only 4 underweight) suggests a consistent over-portioning habit that, over time, creates measurable ingredient waste and cost overruns. Across all branches, the dominance of overweight variance indicates that staff may be defaulting to heavier portions, possibly due to unclear target weight standards or uncalibrated equipment.

5. Improvement Plan

- All branches must conduct immediate equipment calibration checks on all weighing and portioning tools, with results documented and reviewed by branch supervisors weekly throughout May 2026.
- Branch managers should implement mandatory pre-shift weight checks, requiring staff to test and confirm equipment accuracy before any production run begins each day.
- A targeted retraining session on portioning technique and target weight standards should be delivered to all production staff at Mutare Branch within the next two weeks, given its high variance and dual-direction inconsistency.
- Weekly internal audits should be introduced at all branches, with batch weight data reviewed and submitted to the central QC division every Monday for trend monitoring.

6. Conclusion

April 2026 results confirm that weight consistency is a network-wide challenge requiring immediate and coordinated action. No branch met acceptable performance thresholds, and overweight portioning remains the dominant failure mode. With disciplined implementation of the recommended steps, Munandy Bakery can work toward achieving optimal batch rates above 75% by June 2026.

Branch Performance Summary

Branch	Total Batches	Consistency	Avg Var	Rating
Harare	118	55.1%	7.1g	Needs Work
Mutare	125	52.8%	22.4g	Needs Work
Bulawayo	113	57.5%	17.3g	Needs Work

Monthly Highlights

Category	Branch	Performance Summary
Best Performing	Bulawayo	Achieved 57.5% consistency across 113 batches. High quality standards maintained.
Worst Performing	Mutare	Struggled with 52.8% consistency. Management intervention and root cause analysis required.
